Photo-decomposition

#### Abstract

Gold nanoparticles (AuNPs) self-coupled on semiconductors have attracted extensive attentions in the field of catalysis, however, the progress in understanding and optimizing their photocatalytic performance in response to solar light irradiation is limited. In this paper, a series of AuNPs with $\mathrm{Zn}_{2} \mathrm{Al}$-layered double hydroxide (LDH) as support was fabricated via self-assembly routes at room temperature and the tuned oxidation state of AuNPs (as $\mathrm{Au}^{0}, \mathrm{Au}^{3+}$ as well as mixed $\mathrm{Au}^{0} / \mathrm{Au}^{3+}$ ) was revealed to have a crucial effect on establishing their photocatalytic efficiency for the degradation of phenol from aqueous solution under solar irradiation. X-ray absorption near-edge structure (XANES) and extended X-ray absorption fine structure (EXAFS) analyses permitted to characterize the specific interactions of $\mathrm{Zn}_{2} \mathrm{Al}$-LDH with AuNPs and to verify that the state of $\mathrm{Au}^{0} / \mathrm{Au}^{3+} \mathrm{NPs}$ appears due to the electron transfer from $\mathrm{Zn} 2 \mathrm{Al}-\mathrm{LDH}$ to AuNPs when $\mathrm{Zn}_{2} \mathrm{Al}$-LDH reconstruction in the aqueous solution of $\mathrm{Au}\left(\mathrm{O}_{2} \mathrm{CCH}_{3}\right)_{3}$ was achieved under solar irradiation. On the basis of these $\mathrm{AuNPs}-\mathrm{Zn}_{2} \mathrm{Al}$-LDH systems, the possible roles of $\mathrm{Au}^{0}, \mathrm{Au}^{3+}$ or $\mathrm{Au}^{0} / \mathrm{Au}^{3+}$ in establishing synergetic effects with $\mathrm{Zn}_{2} \mathrm{Al}$-LDHs supports for enhancing the photocatalytic response induced by the irradiation with solar light, for manipulating the mechanism, and the catalyst stability in phenol degradation process, are critically discussed.

## 1. Introduction

Gold nanoparticles (AuNPs) have received increasing attentions in catalysis since Hutchings et al. [1] and Haruta et al. [2] demonstrated excellent performances of gold-based catalysts in low-temperature oxidation of CO [3]. AuNPs supported on solids with high surface area are used for a large variety of catalytic reactions, e.g. photocatalysis, cross coupling, sequential oxidative addition, benzylation of aromatics, oxidative $\mathrm{C}-\mathrm{C}$ coupling, amination, and nucleophilic addition [4-8]. The support materials play not only the role of stabilizing AuNPs at different oxidation state $\left(\mathrm{Au}^{\delta+}, \mathrm{Au}^{+}\right.$, or $\left.\mathrm{Au}^{3+}\right)$ or controlling their dispersion level (nanoparticle size) but also might act as a buffer for the electron transfer to AuNPs, and thus to reduce the charge-carrier recombination during the photo-responsive processes [9-11]. Furthermore,

[^0](1) the particle size-dependent photoresponsive characteristics of AuNPs, e.g. surface plasmon resonance (SPR) response, (2) the photo-functionality of the support, and (3) the charge-transfer characteristics from AuNPs to support materials are the recent key issues in designing efficient nano-gold composites as solarresponsive photocatalysts [12-14].

Among the numerous materials of large surface area, layered double hydroxides (LDHs) exhibits unique features not found in other solid supports if used as support materials for AuNPs, thus making AuNPs/LDHs composites specific catalysts [15]. The flexibility of the LDHs composition, their semiconducting characteristics [4], and their high adsorption capacity enables to tune the electronic density at the interface between AuNPs and LDHs. Furthermore, LDHs own a unique self-repairing property to reconstruct its layered structure, after being transformed through calcination into mixtures of metal oxides by the calcination, utilizing its structural "memory effect" to restore original layered structure from mixed oxides. Utilizing the structural memory effect of LDHs, we recently reported a simple, one-step route to fabricate

AuNPs directly on $\mathrm{Zn}-\mathrm{Al}-\mathrm{Ce}$ LDHs [16] and Zn-Ga LDHs [17]. This method used the capability of LDH matrix to form self-supported AuNPs on LDHs, by exploiting the property of LDHs to restore its original layered structure in the aqueous solutions of gold salts, e.g. $\mathrm{AuCl}_{3}$ and $\mathrm{Au}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{3}$, without using any organic additives as surfactant and/or stabilizer for AuNPs.

In a related precedent work, it was revealed that the microscopic morphology of LDHs has an important effect on the location and the size of AuNPs [6]. Recently, Liu and co-workers [7] demonstrated that the synergy between AuNPs and LDHs in AuNPs-Cr-LDHs composites increased if the Cr content was increased in the Cr -LDHs as a support. To date, despite the significant interests in catalysis using the AuNPs composites, maximizing their efficiency under irradiation with solar light still remains a meaningful challenge and the examples in scientific literature are few $[18,19]$. It was demonstrated that the specific charge transfer between AuNPs and a semiconductor support was able to reduce the charge recombination rates and to increase the photocatalytic efficiency [20]. Hence, to design AuNPs-LDHs composites as active photocatalysts under solar irradiation, one of the keys is to establish favourable charge-transfer pathway between the supported AuNPs and LDHs.

Herein, we investigate facile self-assembly routes at room temperature to obtain novel AuNPs- $\mathrm{Zn}_{2} \mathrm{Al}$-LDH photocatalysts with tuned oxidation state of AuNPs, as $\mathrm{Au}^{0}, \mathrm{Au}^{3+}$ as well as a mixture of $\mathrm{Au}^{0} / \mathrm{Au}^{3+}$. Furthermore, X-ray absorption near-edge structure (XANES) and extended X-ray absorption fine structure (EXAFS) analyses permits to demonstrate that the mixed state of $\mathrm{Au}^{0} / \mathrm{Au}^{3+}$ is the result of an electron transfer from $\mathrm{Zn}_{2} \mathrm{Al}$-LDH to AuNPs when $\mathrm{Zn}_{2} \mathrm{Al}$-LDH reconstruction in the aqueous solution of gold acetate was achieved under solar irradiation. To benchmark the suitability of AuNP- $\mathrm{Zn}_{2} \mathrm{Al}$-LDH for solar photocatalysis, they were tested for the phenol photo-decomposition. This reaction is not only a quite well-understood model reaction, but also satisfies an empirical requirement to eliminate a common pollutant, phenol, in the wastewater streams worldwide. We provide compelling evidence that AuNPs are the catalytically active sites for photodegrading phenol under irradiation with simulated solar light although the transfer interactions between AuNPs and $\mathrm{Zn}_{2} \mathrm{Al}$-LDH were crucial to enhance the photocatalytic efficiency.

## 2. Experimental

### 2.1. Synthesis of $L D H$

An aqueous solution of Zn nitrate hexahydrate ( $>99 \%$, Wako Pure Chemical) and Al nitrate nonahydrate ( $>99.9 \%$, Wako Pure Chemical) with the $\mathrm{Zn} / \mathrm{Al}$ atomic ratio of 2.0 in deionized water ( $<0.06 \mu \mathrm{Scm}^{-1}$ ) with the concentration of $\left[\mathrm{Zn}^{2+}\right]+\left[\mathrm{Al}^{3+}\right]=1.2 \mathrm{M}$, an aqueous solution of $\mathrm{NaOH}(1.92 \mathrm{M}$; >97\%, Kanto Chemical), and $\mathrm{Na}_{2} \mathrm{CO}_{3}(0.8 \mathrm{M} ;>99.8 \%$, Wako Pure Chemical) in deionized water were simultaneously added to a flask using a magnetic stirrer at a speed of 900 rates per minute (rpm) for 48 h . The precipitate was filtered and washed with deionized water and dried at 333 K for 24 h [21-23]. The resultant sample was denoted as $\mathrm{Zn}_{2} \mathrm{Al}$-LDH (Table 1a).

### 2.2. AuNPs on $\mathrm{Zn}_{2} \mathrm{Al}$-LDH by the reconstruction method

AuNPs supported on $\mathrm{Zn}_{2} \mathrm{Al}$-LDH was obtained exploring the structural reconstruction of LDH in the aqueous solutions containing $\mathrm{Au}^{3+}$ ions [21]. Namely, $1.20 \mathrm{~g} \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$ powder was calcined in an oven at 773 K for 8 h . The resulted calcined powder was cooled down in the oven till 473 K and slowly added into 250 mL aqueous solution of $\mathrm{Au}(\mathrm{III})$ acetate $(0.10 \mathrm{~g}$ or $0.30 \mathrm{~g} ;>99.9 \%$, Alfa Aesar) with a stirring at a rate of 900 rpm . The reaction mixture

 absorption edge due to the overlap of broad SPR peaks.
was stirred at the rate of 900 rpm and 290 K for 3 h . Then, the precipitate was centrifuged at a speed of 10000 rpm and dried at 358 K. The sample is denoted as $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ (4.8 $\mathrm{wt} \%$ of Au ) and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2$ ( $16 \mathrm{wt} \mathrm{\%}$ of Au ), respectively (Table 1b, c). Separately, after adding the calcined LDH into the $\mathrm{Au}(\mathrm{III})$ acetate $(0.10 \mathrm{~g})$ solution, the resulted suspension was irradiated using a Solar simulator (Model US 800, Unnasol, Germany) for 20 min , stirred at the same rate ( 900 rpm ). The sample is denoted as $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-3-$ Light (Table 1d).

As a comparison, $0.24 \mathrm{~g} \mathrm{Zn}_{2} \mathrm{Al}$-LDH powder was mixed with 250 mL aqueous solution of $\mathrm{Au}(\mathrm{III})$ acetate $(0.020 \mathrm{~g})$ with a stirring at a rate of 900 rpm and irradiated using a Solar simulator for 20 min . Then, the reaction mixture was stirred at a rate of 900 rpm and 290 K for 3 h . Then, the precipitate was filtered using JGWP04700 filter, washed using JGWP04700 filter with deionized water and ethanol (total 250 mL for each), and dried under vacuum at 290 K for 24 h . The sample was denoted as $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Light (4.8 wt\% Au; Table 1g).

### 2.3. AuNPs on $\mathrm{Zn}_{2} \mathrm{Al}$-LDH by impregnation of $\mathrm{HAuCl}_{4}$ followed by liquid reduction

0.044 g of hydrochloroauric acid tetrahydrate ( $>99.9 \%$, Alfa Aesar) was dissolved in 10 mL of deionized water. 0.42 g of $\mathrm{Zn}_{2} \mathrm{Al}-$ LDH was added to the aqueous solution and the mixture was stirred at a rate of 900 rpm and 290 K for 12 h . The precipitate was filtered using a membrane filter (JGWP04700 filter, Omnipore) and washed with deionized water (total 250 mL ), and dried under vacuum at 290 K for 24 h . Obtained powder was added to 10 mL of dehydrated toluene ( $>99.5 \%$, Wako Pure Chemical) and 0.0126 g of $\mathrm{NaBH}_{4}$ ( $>95 \%$, Wako Pure Chemical) was added to the suspension. After stirring for $10 \mathrm{~min}, 3 \mathrm{~mL}$ of ethanol ( $>99.5 \%$, Wako Pure Chemical) was added and the mixture was stirred at a rate of 900 rpm and 290 K for 6 h . The precipitate was filtered and washed using JGWP04700 filter with deionized water and ethanol (total 250 mL for each), and dried under vacuum at 290 K for 24 h [15]. The sample was denoted as $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$ (Table 1e).

Separately, 0.30 g of $\mathrm{Zn}_{2} \mathrm{Al}$-LDH was dispersed in 10 mL of deionized water. To ensure a uniform dispersion, the suspension was ultrasonicated ( $430 \mathrm{~W}, 38 \mathrm{kHz}$ ) for 10 min . Then, 0.031 g of $\mathrm{HAuCl}_{4} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ in aqueous solution $(20 \mathrm{~mL}), 0.036 \mathrm{~g}$ of L-lysine $(98 \%$, Sigma-Aldrich Chemie) in aqueous solution ( 4.0 mL ), and 0.026 g of $\mathrm{NaBH}_{4}$ in aqueous solution ( 2.0 mL ) were added sequentially to the above suspension with a dropping speed of $1.0 \mathrm{~mL} \mathrm{~min}^{-1}$ and stirred at a rate of 900 rpm . Afterwards, dilute hydrochloric acid (Wako Pure Chemical) was added to adjust the pH value to 9.5. The mixed solution was stirred for 1 h and left standing for 24 h . The precipitate was filtered using JGWP04700 filter and washed with deionized water and ethanol (total 250 mL for each), and dried at 333 K for 12 h [24]. The sample was denoted as $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-ImpLysine (Table 1f).

### 2.4. X-ray diffraction (XRD)

XRD pattern was observed using a D8 ADVANCE diffractometer (Bruker) at the Center for Analytical Instrumentation, Chiba University, at a Bragg angle $\left(\theta_{\mathrm{B}}\right)$ of $2 \theta_{\mathrm{B}}=3^{\circ}-60^{\circ}$ with a scan step of $0.01^{\circ}$ and a scan rate of 5 s per step. The measurements were performed at 40 kV and 40 mA using $\mathrm{Cu} \mathrm{K} \alpha$ emission and a nickel filter.

### 2.5. UV-visible spectroscopy

Optical spectroscopic measurements were performed using a UV-visible spectrophotometer (Model V-650, JASCO) using $\mathrm{D}_{2}$ and halogen lamps for wavelengths between 200 and 340 nm and between 340 and 800 nm , respectively. An integrating sphere
(Model ISV-469, JASCO) was used for the diffuse reflectance (DR) measurements. The samples were set in contact with the quartz window glass in a gas-tight DR cell. The measurements were performed at 290 K within the wavelength range $200-800 \mathrm{~nm}$ using 70 mg of sample. DR spectra were converted to absorption spectra on the basis of the Kubelka-Munk equation [22,25,26]. The bandgap value was evaluated on the basis of either simple extrapolation of the absorption edge or the fit to the equation of Davis and Mott [22,26],
$\alpha \times h \nu \propto\left(h \nu-E_{g}\right)^{n}$
in which $\alpha, h$, and $\nu$ are the absorption coefficient, Planck's constant, and the frequency of light, respectively, and $n$ is $1 / 2,3 / 2,2$, and 3 for allowed direct, forbidden direct, allowed indirect, and forbidden indirect transitions, respectively [27].

### 2.6. Transmission electron microscopy (TEM)

High-resolution (HR)-TEM images were observed using a Model $\mathrm{H}-7650$, Hitachi operating at 100 kV . Tungsten filament was used in the electron gun and the samples were mounted on a conducting carbon with Cu grid mesh ( 150 mesh per inch) and the magnification was between 60000 and 200000 times [28].

### 2.7. Au $L_{3}$-edge XANES and EXAFS

Au $L_{3}$-edge XANES and EXAFS spectra were measured at 290 K in a transmission mode on beamline NW10A in the Photon Factory Advanced Ring at the High Energy Accelerator Research Organization (Tsukuba). The storage ring energy was 6.5 GeV and the ring current was 46.6-36.1 mA. A Si (311) double-crystal monochromator and platinum-coated focusing cylindrical mirror were inserted into the X-ray beam path. The X-ray intensity was reduced at $65 \%$ of the maximum flux using a piezo translator set to the crystal to suppress the effects of higher harmonics other than 311 reflection [29]. The slit opening size was 1 mm (vertical) $\times 2 \mathrm{~mm}$ (horizontal) in front of the ionization chamber. The Au $L_{3}$-edge absorption energy was calibrated to 11921.2 eV for the spectrum of Au metal foil [30-32].

The XANES and EXAFS data were analyzed using an XDAP package [33]. The pre-edge background was approximated by a modified Victoreen function $C_{2} / E^{2}+C_{1} / E+C_{0}$. The background of the post-edge oscillation $\mu x$ was approximated by a smoothing spline function and calculated by an equation for the number of data points, where $k$ is the angular wavenumber of photoelectrons.
$\sum_{i=1}^{\text {Data Points }} \frac{\left(\mu x_{i}-B G_{i}\right)^{2}}{\exp \left(-0.075 k_{i}^{2}\right)} \leq$ smoothig factor
Multiple-shell curve-fit analyses were performed for the Fourier-filtered $k^{3}$-weighted EXAFS data in $k$ - and interatomic distance ( $R$ )-space using empirical amplitude extracted from the EXAFS data for $\mathrm{Au}_{2} \mathrm{O}_{3}$ powder and Au metal foil. The $R$ value and its associated coordination number $(N)$ for the $\mathrm{Au}-\mathrm{O}$ and $\mathrm{Au}-\mathrm{Au}$ pairs were set to 0.2013 nm with the $N$ value of 4 and 0.2884 nm with the $N$ value of 12 , respectively [17]. The many-body reduction factor $S_{0}{ }^{2}$ was assumed to be equal for both the sample and the reference.

### 2.8. Brunauer, Emmett, and Teller (BET) surface area measurements

$\mathrm{N}_{2}$ adsorption isotherms were measured at 77.15 K on a Quantachrome Autosorb-1MP automated gas adsorption system. Prior to the measurements, the samples were heated for 12 h under vacuum at 383 K . The BET specific surface area ( $S_{\mathrm{BET}}$ ) was calculated
by using the standard Brunauer, Emmett, and Teller method on the basis of adsorption-desorption data [22,23].

### 2.9. Photocatalytic tests for phenol decomposition

Appropriate amounts of a catalyst were suspended in a phenol solution ( $50 \mathrm{mg}^{-1}$ ) in a batch reactor using a catalyst of $0.5 \mathrm{~g} \mathrm{~L}^{-1}$. The temperature was kept constant at 298 K . After 30 min in darkness to ensure the adsorption equilibrium of phenol on the catalyst, the reactor was irradiated from a solar simulator (Model US 800, Unnasol, Germany) for photocatalytic reaction tests. The sampling of the solution was carried out using a 1 mL pipet every 20 min for 7 h of irradiation. The sampled 1.0 mL of reaction suspension was centrifuged to separate solution from the photocatalyst. The solution was immediately analyzed using UV-visible spectrometer (Model V-550, JASCO) to determine the concentrations of remained phenol and transformed compounds from phenol ( $p$-benzoquinone, muconic acid, catechol, and hydroquinone) [34]. The UV-visible spectra for standard aqueous solution of $p$ benzoquinone (Wako Pure Chemical, $>98 \%$ ), trans,trans-muconic acid (Tokyo Chemical Industry, 98\%), phenol (Wako Pure Chemical, $>99 \%$ ), catechol (Wako Pure Chemical, $>99 \%$ ), and hydroquinone (Wako Pure Chemical, >99\%) were also measured in transmission mode at 290 K .

The peaks in the UV-visible spectra at $197 \mathrm{~nm}, 210 \mathrm{~nm}, 248 \mathrm{~nm}$, and 270 nm were assigned to $\pi-\pi^{*}$ and $n-\pi^{*}$ transition for aromatic ring [35], $p$-benzoquinone, and phenol [36], respectively, and the spectra were deconvoluted using the four Gaussian peaks as follows:

$$
\begin{align*}
& f(x)=a_{1} \exp \left\{-\left(\frac{x-197}{b_{1}}\right)^{2}\right\}+a_{2} \exp \left\{-\left(\frac{x-210}{b_{2}}\right)^{2}\right\} \\
& \quad+a_{3} \exp \left\{-\left(\frac{x-248}{b_{3}}\right)^{2}\right\}+a_{4} \exp \left\{-\left(\frac{x-270}{b_{4}}\right)^{2}\right\} \tag{3}
\end{align*}
$$

The $a_{n}$ and $b_{n}(n=1,2,3,4)$ were the absorbance and peak width in nm, respectively. The $b_{1}, b_{2}, b_{3}$, and $b_{4}$ values resulted in within the range of $6.0-10,11-30,12-30$, and $8.0-22 \mathrm{~nm}$, respectively. To reconfirm the assignment and evaluation of reactants and intermediate compounds, especially phenol and $p$-benzoquinone, the reaction solution was also analyzed high-pressure liquid chromatograph (HPLC; Model Prominence-i, Shimadzu) [37].

## 3. Results

## 3.1. $X R D$

The XRD patterns of $\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}, \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1, \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-2, $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light, $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$, and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Imp-Lysine samples are depicted in Fig. 1. The diffraction peaks common at $2 \theta_{\mathrm{B}}=11.8^{\circ}, 23.6^{\circ}, 34.1^{\circ}, 34.8^{\circ}, 37.5^{\circ}, 39.4^{\circ}, 44.2^{\circ}, 47.0^{\circ}$, $53.2^{\circ}$, and $56.6^{\circ}$ were assigned to $003,006,101,009,1$ $04,015,107,018,100$, and $\frac{1}{2} 11(=01 \overline{1} 1)$ diffractions for the regular layered structure of LDHs. For $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light samples, weak peaks derived from 100 and 101 reflections for wurtzite crystal of ZnO also appeared at $2 \theta_{\mathrm{B}}=31.9^{\circ}$ and $36.4^{\circ}$ (marked with * in Fig. 1), respectively, suggesting the layered structure of LDH was not fully recovered. For $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-2 and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light, a weak peak derived from 111 reflection for face-centered cubic (fcc) crystal of metallic Au was identified at $2 \theta_{\mathrm{B}}=38.3^{\circ}$ (marked with $\boldsymbol{\nabla}$ in Fig. 1).

For all the samples, the major peaks were originated from LDH structure while the peaks due to Au did not appear or were negligibly weak for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1, \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$, and

Fig. 1. XRD pattern for $\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$ (a), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ (b), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2$ (c), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light (d), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$ (e), and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine (f).

Fig. 2. UV-vis absorption spectrum of $\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$ (a), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ (b), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-2 (c), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-3-Light (d), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$ (e), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine (f), and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Light (g).
$\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine above the detection limit of XRD apparatus used. The XRD results indicated that the samples obtained by impregnation followed by liquid reduction ( $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine) did not comprise [mixed] metal oxides of Zn and/or Al (Fig. 1e, f).

### 3.2. UV-visible spectra

UV-visible absorption spectra for the Au-LDHs photocatalysts are depicted in Fig. 2. In the spectra for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1, \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-2, and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light, a peak appeared due to SPR of AuNPs at $539 \mathrm{~nm}, 540 \mathrm{~nm}$, and 547 nm , respectively (Fig. 2b-d). SPR peaks centered at $533-553 \mathrm{~nm}$ were previously reported for 2.9-3.4 nm size of AuNPs embedded on LDH [16]. The red shift of the SPR peak from 539 nm (for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-1) to 547 nm (for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light) suggested the quantum size effect of AuNPs leading to lower-energy plasmonic near-field when AuNPs grew during LDH reconstruction under UV-visible light irradiation.

The band gap values for support materials were evaluated based on Davis-Mott equation (Table 1). The band-gap values for $\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}(5.7 \mathrm{eV}$; Table 1a) apparently decreased to $3.1-2.5 \mathrm{eV}$ for AuNP-LDHs via the reconstruction route (Table 1b-d). It was not due to the change of electronic property of LDH support but can be ascribed to the presence of minor metal oxide phase, e.g. ZnO and/or $\mathrm{ZnAl}_{2} \mathrm{O}_{4}$ and/or the synergetic effects of AuNPs with $\mathrm{ZnO} / \mathrm{ZnAl}_{2} \mathrm{O}_{4} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$. In the UV-visible spectra of $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Imp- $\mathrm{NaBH}_{4}$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine (Fig. 2e, f), the characteristic absorption edge at $\sim 400 \mathrm{~nm}$ did not appear. This absorption edge is due to ZnO and/or spinel metal oxides: $\mathrm{ZnAl}_{2} \mathrm{O}_{4}$. Thus, both the XRD and UV-vis absorption results suggested the jointed phases of major LDHs and minor mixed oxides for AuNPs-LDHs composites

Fig. 3. Normalized $\mathrm{AuL}_{3}$-edge XANES spectra for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec- 1 (a), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}$ 2 (b), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-3-\operatorname{Light}(\mathrm{c}), \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$ (d), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Imp-Lysine (e), Au metal foil (f), and $\mathrm{Au}_{2} \mathrm{O}_{3}$ (g).

Fig. 4. Comparison of the $\mathrm{Au} \mathrm{L}_{3}$-edge XANES spectra for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light (a) and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$ (b) to the combination of standard spectra of Au metal foil ( $\mathrm{Au}^{00}$ ) and $\mathrm{Au}_{2} \mathrm{O}_{3}\left(\mathrm{Au}^{3+}\right)$. The mixing ratio of $\mathrm{Au}^{00}: \mathrm{Au}^{3+}$ was progressively varied: 0:100 (c), 55:45 (d), 65:35 (e), 75:25 (f), 85:15 (g), 95:5 (h), and 100:0 (i).
obtained by the LDH reconstruction method. The special environment provided by the transformation of the mixed oxides ( ZnO and/or $\mathrm{ZnAl}_{2} \mathrm{O}_{4}$ ) into the layered LDH structure might give rise to specific photo-responsive properties for the AuNPs-LDHs composites. For $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine, the SPR peak due to Au was located at 536 nm and 537 nm , respectively (Fig. 2e, f). The UV-visible spectrum for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Light was rather featureless and a weak, broad SPR peak appeared at 552 nm .

As will be described based on $\mathrm{Au} \mathrm{L}_{3}$-edge XANES (see section 3.3), Au -LDHs comprising $\mathrm{Au}^{0}$ sites ( $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-3$-Light, $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Imp- $\mathrm{NaBH}_{4}$, and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine) exhibited relatively intense SPR peaks (Fig. 2d-f) in clear contrast to weaker SPR peaks for the composites comprising exclusive $\mathrm{Au}^{3+}$ sites ( $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2$; Fig. 2b, c).

## 3.3. $A u L_{3}$-edge XANES

Au $\mathrm{L}_{3}$-edge XANES spectra measured for Au -LDH composites are depicted in Fig. 3. The spectrum patterns for both $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec1 and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-2 (spectra a, b) were quite similar to that of $\mathrm{Au}_{2} \mathrm{O}_{3}$ (spectrumg) while the spectrum e for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine was similar to that of Au metal foil (spectrum f). On the other hand, the post-edge pattern for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp$\mathrm{NaBH}_{4}$ (spectra c and d) was that between that of $\mathrm{Au}^{00}$ and $\mathrm{Au}^{3+}$, demonstrating that the Au sites in these two catalysts were the mixture of $\mathrm{Au}^{0}$ and $\mathrm{Au}^{3+}$. The spectra for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$ were fitted with the standard spectra f and g of Au metal $\left(\mathrm{Au}^{0}\right)$ and $\mathrm{Au}_{2} \mathrm{O}_{3}\left(\mathrm{Au}^{3+}\right)$ by progressively changing the mixing ratio of the two spectra (Fig. 4). The spectra of Fig. 3c and $d$ most resembled mixed spectra with the mixing ratio of $\mathrm{Au}^{0}$ : $\mathrm{Au}^{3+}=65: 35$ (Fig. 3e) and 85:15 (Fig. 3 g), respectively.
(A) Reconstructed Au/LDHs

(B) Impregnated Au/LDHs

Scheme 1. Proposed reaction mechanism of photocatalytic phenol decomposition on gold species formed on LDH via reconstruction (A) or impregnation (B). Indirect path via $p$-benzoquinone also took place for B , but the rates were lower than those for A . The reaction paths from o-benzoquinone or muconic acid to $\mathrm{CO}_{2}$ are unknown.

The Au sites were reduced to $\mathrm{Au}^{0}$ in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine by the effects of $\mathrm{NaBH}_{4}$ and/or lysine. On the other hand, the formation of $\mathrm{Au}^{0}$ in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}$-3-Light was the consequence of the electron transfer from $\mathrm{Zn}_{2} \mathrm{Al}$ LDH to AuNPs resulted from the charge separation occurred under the irradiation of UV-visible light. Previous results showed that the charge transfer between $\mathrm{TiO}_{2}$ and the supported AuNPs [38] and between ZnO and the supported Cu ions [28] should suppress the charge recombination thus to maximize its photocatalytic response at surface. Based on these results, the specific charge transfer processes between AuNP and $\mathrm{Zn}_{2} \mathrm{Al}$-LDH in the $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light sample might improve the photocatalytic efficiency.

### 3.4. TEM

Fig. 5 shows representative TEM images and the particle size distribution for AuNPs. Table 1 listed the mean diameter values. TEM images indicated that almost spherical NPs were densely distributed on the $\mathrm{Zn}_{2} \mathrm{Al}$-LDH surface. The mean sizes of the AuNPs were 4.7 nm and 4.9 nm for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec2, respectively, while mean size for AuNPs increased to 8.5 nm for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light (Fig. 5a-c and Table 1b-d). Furthermore, together with XANES and TEM results, it was suggested that particle size distribution of AuNPs consisted of $\mathrm{Au}^{3+}$ for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-3-Light negligibly change from that of $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ while under solar irradiation greater AuNPs consisted of $\mathrm{Au}^{0}$ than $\sim 5 \mathrm{~nm}$ were formed. Thus, particle size distribution for the AuNPs comprising mixed valences of $\mathrm{Au}^{00} \& \mathrm{Au}^{3+}$ in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light became wider (Fig. 5c). This result reveals an intimate interaction of $\mathrm{Au}^{3+} \mathrm{NPs}$ with the $\mathrm{Zn}_{2} \mathrm{Al}$-LDH surface during the restoration of the LDH in which $\mathrm{Au}^{3+} \mathrm{NPs}$ supported on $\mathrm{Zn}_{2} \mathrm{Al}$-LDH would be able to accept electrons quite effectively from the LDH surface to form $\mathrm{Au}^{00} \mathrm{NPs}$ (Scheme 1A). To obtain more detailed information about the interactions between AuNPs and LDH surface, Au L ${ }_{3}$-edge EXAFS was employed to monitor the local structure for Au (see Section 3.5).

For AuNP-LDHs composites obtained by impregnation method the mean diameter of self-supported AuNPs were 4.1 nm for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$ and 7.3 nm for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine (Fig. 5d, e and Table 1e, f).

Fig. 5. TEM images and analysis for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Rec}-1$ (a), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Rec}-2$ (b), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-3$-Light (c), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH} 4$ (d), and $\mathrm{Au} / \mathrm{Zn} 2 \mathrm{Al}-\mathrm{Imp}-\mathrm{Lysine}(\mathrm{e})$.

## 3.5. $\mathrm{Au} L_{3}$-edge EXAFS

The coordination environment of AuNPs in AuNP-Zn $n_{2}$ Al-LDH was investigated based on the Au- $L_{3}$ edge EXAFS. The $k^{3}$-weighted EXAFS function was depicted in Fig. 6. The peaks at 0.16 nm and 0.28 nm (phase shift uncorrected) in the Fourier transform were curve-fit with the parameters of $\mathrm{Au}-\mathrm{O}$ and $\mathrm{Au}-\mathrm{Au}$ interatomic pairs, respectively (Fig. 6b, d).

The best-fit results were listed in Table 2 . The $N$ value of $\mathrm{Au}-\mathrm{O}$ for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-3$-Light was 1.6 and that for $\mathrm{Au}-\mathrm{Au}$ was 9.0 (Fig. 63 and Table 2c), significantly smaller than $N$ values for models of $\mathrm{Au}_{2} \mathrm{O}_{3}$ ( 4 ; Table 2f) and Au metal (12; Table 2 g ). Namely, the $N$ value of $\mathrm{Au}-\mathrm{O}$ for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light was $38-43 \%$ of $N$ value for model $\mathrm{Au}_{2} \mathrm{O}_{3}$ crystallines taking the fit error values into account. Similarly, the $N$ value for $\mathrm{Au}-\mathrm{Au}$ in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light was $65-85 \%$ of that for Au metal foil taking the fit error values into account.

On the other hand, the $N$ values of $\mathrm{Au}-\mathrm{O}$ for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-2 samples (both 3.7, Table $2 \mathrm{a}, \mathrm{b}$ ) was much closer to that of $\mathrm{Au}-\mathrm{O}$ in $\mathrm{Au}_{2} \mathrm{O}_{3}$. These results demonstrated that the fabrication of the catalyst under irradiation from solar simulator decreased the $N$ values of both $\mathrm{Au}-\mathrm{Au}$ and $\mathrm{Au}-\mathrm{O}$ shells. Previous studies reported that the decreased $N(\mathrm{Au}-\mathrm{Au})$ values in AuNPs -LDHs composites indicate stronger interactions between the nanosized Au and LDHs surface [20]. Thus, $\mathrm{Zn}_{2} \mathrm{Al}$-LDH reconstruction in the aqueous solution of Au acetate under the irradiation of UV -visible light should give rise to closer interactions between $\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$ and the supported Au nanoparticles.

The mean particle size for Au suggested by $N(\mathrm{Au}-\mathrm{Au})$ value for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light (9.0; Table 2 c ), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$ (11.3; Table 2d), and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine (11.8; Table 2e) were $2.5 \mathrm{~nm}, 4.8 \mathrm{~nm}$, and 5.3 nm , respectively, assuming fcc crystalline packing [39]. These values were significantly smaller than those obtained using TEM images ( $8.5 \mathrm{~nm}, 4.1 \mathrm{~nm}$, and 7.3 nm , respectively, Table 1d-f). The reasons of this discrepancy would be that smaller NPs were not observable in TEM and thus TEM tends to overestimate the nanoparticle size and/or that the size of Au
oxides was neglected in the estimation based on $N(\mathrm{Au}-\mathrm{Au})$ values of EXAFS. In fact, the mean values by TEM ( 7.3 nm ) and by EXAFS ( 5.3 nm ) were relatively close for exclusive $\mathrm{Au}^{00} \mathrm{NPs}$ in $\mathrm{Au} / \mathrm{Zn} \mathrm{n}_{2} \mathrm{Al}-$ Imp-Lysine (Table 1f).

Only Au-Au peak was observed for Au/LDHs obtained by impregnation method (Fig. 6-4, 6-5 and Table 2d, e). Thus, EXAFS results provided further evidence for direct interactions of the surface self-supported AuNPs and $\mathrm{Zn}_{2} \mathrm{Al}$-LDH layers.

### 3.6. BET surface area

The $S_{\text {BET }}$ value was $97 \mathrm{~m}^{2} \mathrm{~g}^{-1}$ for $\mathrm{Zn}_{2} \mathrm{Al}$-LDH (Table 1a) in consistent with reported values for LDHs of similar composition (33-83 $\mathrm{m}^{2} \mathrm{~g}^{-1}$ ) [22,23]. The value decreased by a factor of 0.61-0.84 times for reconstructed LDH samples in the presence of Au (Table $1 \mathrm{~b}-\mathrm{d}$ ) or by a factor of $0.56-0.69$ times for impregnated $\mathrm{Au} / \mathrm{LDHs}$ (Table 1e, f). The decrease was not simply correlated to the preparation method of catalysts or Au contents (Table 1).

### 3.7. Photocatalytic tests

Phenol was chosen as a molecule to represent toxic organic compounds with low degradability. The suitability of AuNPs-Zn $n_{2} \mathrm{Al}-$ LDHs for photocatalytic decomposition of phenol was evaluated from aqueous solutions under irradiation with simulated solar light. Fig. 7 shows the evolution of the UV-visible absorption profiles for reaction solution during the course of irradiation time. Blank tests without photocatalyst or solar light revealed negligible photocatalytic activities less than $99 \%$ degradation of phenol, verifying that phenol degradation reaction was driven via photocatalytic process.

For all the AuNPs- $\mathrm{Zn}_{2} \mathrm{Al}$-LDH catalysts, the characteristic absorbance at 270 nm for phenol decreased as the photo-reaction time elapsed. Unsupported $\mathrm{Zn}_{2} \mathrm{Al}$-LDH exhibited only $7.6 \%$ of decrease at 5 h of irradiation from the phenol absorbance at 0 min (Fig. 7a), demonstrating that only LDH was insufficient for degrad-

Fig. 6. Au $\mathrm{L}_{3}$-edge EXAFS for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ (1), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2$ (2), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light (3), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}(4)$, and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}$-Lysine (5). $k^{3}$-weighted EXAFS $\chi$ oscillation (a), its associated Fourier transform (b), and best-fit results in $k$-space (c) and $R$-space (d). The red (or thin) line represents the experimental values, and the blue (or thick) line represents calculated values in panels $b$ and $d$. The solid line represents the magnitude and the dotted line represents the imaginary part in panels c and d . (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)
ing phenol under solar light. This fact indicates the essential contribution of AuNPs to the photocatalytic process.

It was established that phenol photodecomposition could follow different pathways following either a direct oxidative opening process of the aromatic ring, in which muconic acid is formed from o-benzoquinone, or an indirect ring cleavage process to hydroxylated phenolic intermediates e.g. p-benzoquinone/hydroquinone as primary intermediate species [36,39]. The peaks at 246,263 , 270,275 , and 289 nm were reported to appear in the UV absorption region for $p$-benzoquinone, trans, trans-muconic acid, phenol, catechol, and hydroquinone [36,40] and in fact confirmed for $4.3-74 \mathrm{ppm}$ of standard aqueous solutions (Fig. 7h). In this regard, differences were observed between the Au-LDH composite catalysts obtained by reconstruction and impregnation methods. Namely, for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec- $1, \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-3-Light (Fig. 7b-d), formation of $p$-benzoquinone, identified as a characteristic absorption at 248 nm , showed that phenol degradation underwent through hydroxylated phenolic intermediates (Fig. 8B) versus both indirect and direct opening process of aromatic using $\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$ and impregnated Au photocatalysts on LDH (Fig. 7a, e-g). The peak intensity was evaluated based on peak deconvolution using equation 3 as a function of wavelength. Quan-
tum mechanically, it would be strict to deconvolute peaks as a function of wave number, i.e. the dimension of energy. The time course in Fig. 7d was replotted as a function of wave number (Fig. S1). It looks almost identical to Fig. 7d except for the direction of horizontal axis is inverse and we believe that the fit using equation 3 as a function of wavelength makes sense.

For reconstructed Au-LDHs, the peak intensity at 248 nm reached a maximum at $40-60$ min from the start of irradiation (Fig. 8B-b-d), however, corresponding peak due to hydroquinone at 288 nm was not detected during the time course probably due to the quick oxidative conversion to thermodynamically more stable $p$-benzoquinone. Among them, $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light was the most active based on the decrease of phenol absorbance at 270 nm (Fig. 8A-d). Interestingly, for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2$, the peak intensity of $p$-benzoquinone decreased for initial 4 h but instead slightly increased after 5 h of irradiation (Fig. 8B-c). It appears that most likely cause was the balance of the rates of phenol photooxidation and the redox equilibrium between hydroquinone and $p$-benzoquinone:
$\mathrm{HO}($ surface $)+h^{+} \rightarrow{ }^{\bullet} \mathrm{OH}$
Phenol $+{ }^{\bullet} \mathrm{OH}+h^{+} \rightarrow$ Hydroquinone $+\mathrm{H}^{+}$

Table 2

Hydroquinone $+2 h^{+} \rightarrow$ p-Benzoquinone $+2 \mathrm{H}^{+}$
$p$-Benzoquinone $+6 \mathrm{O}_{2} \rightarrow \ldots \rightarrow 6 \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}$.
For $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine, we clearly observed the increase in the broadness of the absorption around 270 nm . This suggests the formation of muconic acid ( 260 nm ) and catechol $(276 \mathrm{~nm})$ in addition to phenol $(270 \mathrm{~nm})$ in the reaction solution. Thus in the proposed reaction path for the second group, in addition to initial indirect ring opening via $p$-benzoquinone based on the $248-\mathrm{nm}$ peak maximum at $20-40 \mathrm{~min}$ from the start of irradiation (Fig. 8B-a, e-g), the oxidation of catechol to o-benzoquinone and the direct opening of the aromatic ring of o-benzoquinone to muconic acid also occurred [36]:

Phenol $+\cdot \mathrm{OH}+h^{+} \rightarrow$ Catechol $+\mathrm{H}^{+}$
Catechol $+2 h^{+} \rightarrow$ o-Benzoquinone $+2 \mathrm{H}^{+}$
$o$-Benzoquinone $+2 . \mathrm{OH} \rightarrow$ muconicacid
muconicacid $+11 / 2 \mathrm{O}_{2} \rightarrow \ldots \rightarrow 6 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}$.
Thus, different reaction paths were revealed between these two types of catalysts. Fig. 8 shows the results for measured absorbance of each deconvoluted peak using Gaussian functions. The activity sequence of the catalysts after 160 min of irradiation under UV-visible light was in the order (phenol degradation ratio in the parenthesis):

$$
\begin{align*}
& \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\text { Rec-3-Light }(100 \%)>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Rec}-1(70.1 \%)> \\
& \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Light}(52.3 \%)>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Rec}-2(25.4 \%) \\
& \sim \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Imp}-\mathrm{NaBH}_{4}(26.0 \%) \sim \mathrm{Au} / \mathrm{Zn}_{2} \\
& \mathrm{Al}-\text { Imp-Lysine }(22.5 \%)>\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}(17.6 \%) . \tag{12}
\end{align*}
$$

$\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light was the most active in degrading phenol under simulated solar irradiation. The major reaction routes via equations 4-7 based on the monitoring using UV-visible spectroscopy should be confident with the confirmation of peaks of phenol and $p$-benzoquinone by HPLC equipped with a column Shim-pack VP-ODS using the mixed solution of acetonitrile and

10 mM sodium phosphate buffer as a carrier. However, the calibration of the amount only for $p$-benzoquinone was difficult in the standard mixed solutions of $p$-benzoquinone ( $0.1-2.0 \mathrm{ppm}$ ), trans,trans-muconic acid ( $0.1-2.0 \mathrm{ppm}$ ), phenol ( $5.0-100 \mathrm{ppm}$ ), catechol ( $5.0-100 \mathrm{ppm}$ ), and hydroquinone ( $5.0-100 \mathrm{ppm}$ ) presumably due to the equilibrium between $p$-benzoquinone and hydroquinone (equation 6). The calibration of hydroquinone using HPLC was confident due to the difference of sensitivity (molar absorption coefficient) between $p$-benzoquinone and hydroquinone (Fig. 7h). This equilibrium may be also related to the fact that no hydroquinone peak was observed in the photo-decompsition monitoring using UV-visible spectroscopy (Fig. 7a-g). Improved HPLC analyses will be published elsewhere [41].

Furthermore, photodecomposition of acetophenone ( $25 \mathrm{mg} \mathrm{L}^{-1}$ ) was also monitored to check the availability of UV-visible monitoring for the other catalytic reaction (Supplementary data). The reactivity order was

$$
\begin{align*}
& \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al} \text {-Rec-3-Light }>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al} \text {-Light }> \\
& \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}, \tag{13}
\end{align*}
$$

similar as in equation 12.
$\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ showed slightly less catalytic activity with $70 \%$ phenol degradation ratio of that using $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light for 160 min of reaction. Note that $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light, $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-1, and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Light have essentially identical chemical compositions in LDH and also Au content although chemical states were different in AuNPs: a mix state of $\mathrm{Au}^{0}$ and $\mathrm{Au}^{3+}$ in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-3$-Light versus exclusive $\mathrm{Au}^{3+}$ in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec- 1 . Hence, balancing the oxidation state of AuNPs should clearly influence the photocatalytic performance.

Increasing Au content in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-2 steadily declined the phenol degradation ratio to $25 \%$ for 160 min of reaction (Fig. 8Ac) and p-benzoquinone was accumulated (Fig. 8B-c). Furthermore, $\mathrm{Au}-\mathrm{Zn}_{2} \mathrm{Al}$ catalysts obtained by impregnation-reduction method showed slightly less photocatalytic activity, with $26-23 \%$ phenol degradation over the same time frame. For quantitative comparison between the catalysts, specific rates ( $\mu \mathrm{mol} \mathrm{L}^{-1} \mathrm{~h}^{-1}$ ) were calculated based on the derivative of phenol amount as a function of time

Fig. 7. UV-vis absorption spectrum of phenol photo degradation time course for $\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$ (a), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1$ (b), $\mathrm{Au} / \mathrm{Zn} 2 \mathrm{Al}-\mathrm{Rec}-2$ (c), $\mathrm{Au} / \mathrm{Zn} 2 \mathrm{Al}-\mathrm{Rec}-3-\mathrm{Light}(\mathrm{d}), \mathrm{Au} / \mathrm{Zn} n_{2} \mathrm{Al}-$ Imp- $\mathrm{NaBH}_{4}$ (e), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine (f), $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Light (g), p-benzoquinone (4.3 ppm; h1), trans, trans-muconic acid (5.0 ppm; h2), phenol ( 67 ppm ; h3), catechol ( 74 ppm ; h 4 ), and hydroquinone ( 68 ppm ; h5).

## (Table 1):

$$
\begin{align*}
& \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al} \text {-Rec-3-Light(199) }>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Rec}-1(125)> \\
& \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Light}(68)>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2(47) \sim \mathrm{Au} / \mathrm{Zn}_{2} \\
& \text { Al-Imp- } \mathrm{NaBH}_{4}(42) \sim \mathrm{Au} / \mathrm{Zn}_{2} \\
& \text { Al-Imp-Lysine (43) }>\mathrm{Zn}_{2} \mathrm{Al} \text {-LDH(25). } \tag{14}
\end{align*}
$$

It was also apparent from the rates that $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light showed a maximum rate for phenol degradation and the order of the rates was essentially identical to the order of degradation extent in equation 12 . The results showed that $\mathrm{Au}^{0}$-based catalysts were
approximately four orders of magnitude less active than $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$ -Rec-3-Light comprising a mixed valence state of $\mathrm{Au}^{0} / \mathrm{Au}^{3+}$.

In fact, the numbers of surface-exposed $\mathrm{Au}^{0}$ sites were estimated for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light, $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp- $\mathrm{NaBH}_{4}$, and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine based on mean Au particle size by TEM and cubo-octahedron model [42] (Table 1d-f). The values $27 \mu \mathrm{molg}_{\mathrm{cat}^{-1}}, 31 \mu \mathrm{molg}_{\mathrm{cat}^{-1}}{ }^{-1}$, and $19 \mu \mathrm{molg} \mathrm{cat}^{-1}$, respectively, show no correlation to photocatalytic rates of phenol decomposition. Furthermore, BET surface area was evaluated for catalysts after phenol photodecomposition tests for 5 h (Table 1). The activity order is written again with the BET surface area in the parenthesis:

Fig. 8. The time course for peak at 270 nm (phenol; A) and at 248 nm ( $p$-benzoquinone; B) evaluated based on Gaussian deconvolution during phenol photo-degradation for

Fig. 9. The photocatalytic activity for six cycles of phenol decomposition. Before the 6 th cycle, the catalyst was kept during 1 h under solar irradiation using $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-3-Light.

$$
\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-3-\operatorname{Light}\left(79 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right)>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1
$$

$$
\left(81 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right)>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\operatorname{Rec}-2\left(59 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right)
$$

$$
\sim \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}\left(54 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right) \sim \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-
$$

$$
\begin{equation*}
\text { Imp-Lysine }\left(67 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right)>\mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}\left(97 \mathrm{~m}^{2} \mathrm{~g}^{-1}\right) \tag{14'}
\end{equation*}
$$

It was difficult to find the correlation between the BET surface area and he photocatalytic activity order. Thus, $\mathrm{Au}^{0}$ sites and specific surface area were directly not related to photocatalytic activity.

We also noticed that $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light showed the highest intensity for the SPR response of AuNPs (see Fig. 2d), although a systematic correlation between the SPR intensity of the self-supported AuNPs and the photocatalytic efficiency of the studied catalysts was not found mostly due to the difference of SPR response between $\mathrm{Au}^{0}$ and $\mathrm{Au}^{3+}$ sites. Furthermore, as shown in Table 1b, c, and e, there was no remarkable difference in AuNPs mean particles sizes of $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1, \mathrm{Au} / \mathrm{ZnAl}-\mathrm{Rec}-2$, and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Imp- $\mathrm{NaBH}_{4}$ ( $4.1-4.9 \mathrm{~nm}$ ) based on TEM images. On the other hand, a slight variation was observed for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine with a mean size of AuNPs of 8.5 and 7.3 nm , respectively (Table 1d, f). Thus, small extent of increase of AuNPs mean size affected no impact on the photocatalytic activity.

In view of its application, the stability of the photocatalyst is also important and needs to be evaluated. The best $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Rec-3-Light photocatalyst was tested for the reusability. Fig. 9 shows the recycling experiments of $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light for phenol degradation under solar irradiation. The degradation rates
using photocatalysts were $100 \%, 91.2 \%, 86.8 \%, 78.9 \%$, and $72.8 \%$ in the first, second, third, fourth, and fifth cycle of tests ( 160 minirradiation for each cycle). The catalyst efficiency still remained at $73 \%$ of initial activity after the fifth successive recycle tests. Furthermore, the used $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light sample was separated from the reactor after the fifth cycle and irradiated for 1 h under UV-visible light. After the light treatment, the catalyst was tested again for phenol photo-decomposition. Confidently, the efficiency for phenol degradation increased to $80.9 \%$ of initial activity, increased from $72.8 \%$ in the fifth cycle. This behavior might be relied on the particular charge transfers in the intimately mixed phases of AuNPs and $\mathrm{Zn}_{2} \mathrm{Al}$-LDHs evolved under the irradiation with UV-visible light.

AuNPs leaching, a possible explanation for the decrease in efficiency was independently ruled out by centrifuging the reaction mixture after each cycle. No further reaction of phenol was observed when the supernatant was mixed with the fresh phenol solution under the solar irradiation, demonstrating a minimal/no contribution from leached AuNPs. Furthermore, the UV-visible analysis of the supernatant did not detect SPR effect of AuNPs pointing out that nano-sized gold species was not present in the supernatant. The leaching of Zn or Al from the LDH layers might occur only at acidic pH (lower than 3) while the pH of the phenol aqueous solutions used during the experiments (containing also the catalyst) was around 7.5.

## 4. Discussion

### 4.1. Electronic and structure characteristics of AuNPs on AuNPs/LDHs interface

Photocatalytic phenol decomposition rates followed the order of equation 12. Basically, photocatalysts comprising Au embedded during the reconstruction of LDH layers were superior to impregnated Au on LDH using chemical reductant and/or surfactant or unsupported LDH (Fig. 8). Typical difference between these two groups was the valence state of Au atoms in AuNPs: major valence state was $\mathrm{Au}^{3+}$ in the former AuNP-LDHs via reconstruction route versus major metallic $\mathrm{Au}^{0}$ state in the latter Au photocatalysts impregnated on LDH based on $\mathrm{Au}_{\mathrm{L}_{3}}$-edge XANES.

In the photocatalytic activity order of phenol decomposition in equation $12, \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light was especially active and $30 \mathrm{mg} \mathrm{L}^{-1}$ of phenol was completely decomposed to lower than detection limit within 160 min of UV-visible light irradiation (Figs. 7 d and 8 d ). The valence state of Au was evaluated to $\mathrm{Au}^{0}$ : $\mathrm{Au}^{3+}$ of 65: 35 based on the comparison to the mixture of $\mathrm{Au} \mathrm{L}_{3}-$
edge XANES spectra for Au metal and $\mathrm{Au}_{2} \mathrm{O}_{3}$ by changing the mixing ratio of the two (Fig. 4a, e).

The coordination of Au sites in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light was further investigated by Au L $\mathrm{L}_{3}$-edge EXAFS analyses (Fig. 6-3). Both $\mathrm{Au}-\mathrm{Au}$ and $\mathrm{Au}-\mathrm{O}$ peaks in the Fourier transform were clearly observed only for this sample among the AuNP-LDH samples via reconstruction. In fact, both Au-O peak with the $N$ value of 1.6 (4 for $\mathrm{Au}_{2} \mathrm{O}_{3}$ crystallites) and $\mathrm{Au}-\mathrm{Au}$ peak with the $N$ value of 9.0 (12 for Au metal) were given based on the curve-fit analysis (Table 2c). These reduced $N$ values compared to bulk crystallites/crystals suggested mean 8.5 nm of AuNPs embedded on LDH surface (TEM, Fig. 5 c). The reconstruction of LDH was taking place in a complex environment in which the mixture of ZnO and $\mathrm{ZnAl}_{2} \mathrm{O}_{4}$ was able to reconstruct the brucite-like $\mathrm{Zn}_{2} \mathrm{Al}$-LDH layers. Such a specific environment might facilitate particular phases junctions between $\mathrm{ZnO} / \mathrm{ZnAl}_{2} \mathrm{O}_{4} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{LDH}$ and the evolved AuNPs where $\mathrm{Au}^{3+}$ ions should bind with their surface to constitute thin $\mathrm{Au}_{2} \mathrm{O}_{3}$ interface phase and diffused electrons originating from the charge separation by UV-visible light irradiation during the reconstruction process should reduce surface Au sites to $\mathrm{Au}^{0}$ (Scheme 1A). The interface of $\mathrm{Au}_{2} \mathrm{O}_{3}$ phase between metallic $\mathrm{Au}^{0}$ and LDH might facilitate the electron transfer from semiconducting LDH to Au sites for $\mathrm{O}_{2}$ reduction during aerobic phenol photo-decomposition whereas the metallic $\mathrm{Au}^{0}$ NPs were not effectively embedded on the LDH surface for impregnated AuNP-LDH samples thereby the electron transfer at the interface was slower and the charge separation efficiency was lower.

Furthermore, the comparison of Debye-Waller factors ( $\Delta \sigma^{2}$ ) obtained in EXAFS analysis revealed that $\mathrm{Au}^{0}$ had a higher disorder in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light ( $\Delta \sigma^{2} \mathrm{Au}-\mathrm{Au}: 0.3 \times 10^{-5} \mathrm{~nm}^{2}$ ) than in the AuNP-LDHs obtained via impregnation ( $\Delta \sigma^{2} \mathrm{Au}-\mathrm{Au}$ : $0 \times 10^{-5} \mathrm{~nm}^{2}$ and $0.18 \times 10^{-5} \mathrm{~nm}^{2}$ ) due to specific interaction between AuNP and LDH during reconstruction [43] while the $\mathrm{Au}-\mathrm{O}$ showed the lowest disorder in $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light ( $\Delta \sigma^{2}$ $0.1 \times 10^{-5} \mathrm{~nm}^{2}$ ) compared to other reconstructed AuNP-LDHs ( $\Delta \sigma^{2} 0.3 \times 10^{-5}-0.8 \times 10^{-5} \mathrm{~nm}^{2}$ ) comprising dominant $\mathrm{Au}^{\mathrm{III}}$ sites probably due to the difference between the Au oxide interface sites and Au oxide NP sites.

### 4.2. Proposed reaction mechanism of phenol photodecomposition utilizing various states of Au on LDH

The other difference between the first group, AuNP-LDHs via reconstruction, and the second group, obtained by impregnation of Au on LDH, was the photocatalytic reaction pathway: via indirect ring cleavage mechanism to p-benzoquinone and/or other hydroxylated phenolic intermediates versus both indirect and direct oxidative ring opening processes, respectively. Thermodynamically more stable p-benzoquinone compared to hydroquinone would be formed via reaction of phenol with a hole and hydroxy radical (produced from a hole \& surface hydroxy; equation 4) to hydroquinone (equation 5) on LDH surface under the irradiation of UV-visible light followed by further two electron oxidation by holes to p-benzoquinone (equation 6). These oxidation reaction steps would be accelerated by the effective charge transfer at the interface between AuNPs and LDH and the resultant better charge separation efficiency as the assembly. Using anatase-type $\mathrm{TiO}_{2}$, boron-doped anatase $\mathrm{TiO}_{2}$, and Au and/or Pd -doped $\mathrm{TiO}_{2}$ under UV-visible light, a peak at 289 nm due to hydroquinone gradually increased associated with the decrease of peak decrease at 270 nm due to phenol, but any clear peak at 248 nm due to p-benzoquinone was not observed [31,44]. This difference suggested that the photooxidation from hydroquinone to p-bezoquinone was favorable over LDH surface (Scheme 1A) versus significant photo-reduction from p-benzoquinone to hydroquinone over $\mathrm{TiO}_{2}$-based photocatalysts. The stabilization of p-benzoquinone was also pointed out for
$\mathrm{CeO}_{2}-\mathrm{ZnTi}-\mathrm{LDH}$ photocatalyst via LDH reconstruction route [36]. However, the photocatalytic contribution of impurity level of metal oxide phases, e.g. ZnO and $\mathrm{ZnAl}_{2} \mathrm{O}_{4}$, detected for the first group, AuNP-LDHs via reconstruction, as detected for active photocatalysts in XRD (Fig. 1b, d) cannot be totally excluded because the charge separation efficiency using metal oxides is in general superior to that using metal hydroxides.

In the second group of photocatalysts, the peak due to pbenzoquinone at 248 nm appeared after $20-40 \mathrm{~min}$ suggesting indirect ring opening, however the peak was weaker (Fig. 8B-a, $\mathrm{e}-\mathrm{g})$ than that in the first group, especially for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light (Fig. 8B-c, d), suggesting that direct ring cleavage mechanism also proceeded. In fact, the minor contribution of muconic acid ( 260 nm ) and catechol ( 276 nm ) was suggested based on the broader peak width centered at 270 nm (phenol), especially for $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH}_{4}$ and $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Imp-Lysine during the time course of phenol decomposition irradiated by light (Fig. 7a, e-g). It should be noted that p-benzoquinone was detected after $40-60 \mathrm{~min}$ for the first group but that the phenol decomposition rates to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ (equation 7) was faster using first group, especially using $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light: total mineralization at 160 min (Fig. 7d). Thus, the rates from phenol to p-benzoquinone (Scheme 1A) should be significantly accelerated for the first group compared to the rates from phenol to muconic acid (Scheme 1B) due to greater amount of diffused holes owing to the effective charge separation for reconstructed AuNP-LDH assembly.

This study provides experimental evidence that to design efficient AuNPs-LDHs for solar energy photocatalysis the tailored construction for specifically designed the characteristics of the phase junctions between AuNPs and LDH is required.

## 5. Conclusions

AuNPs formed via reconstruction route of LDH in $\mathrm{Au}(\mathrm{III})$ acetate aqueous solution was compared to AuNPs impregnated on LDH and reduced by $\mathrm{NaBH}_{4}$ and/or lysine. The LDH reconstruction was performed in the presence/absence of UV-visible light. AuNPs impregnated in LDH in the presence of UV-visible light were also prepared from comparison. The activity of phenol photo-decomposition was in the order $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light<span> $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-1>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$ Light $>\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Rec}-2 \sim \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-\mathrm{Imp}-\mathrm{NaBH} \mathrm{H}_{4} \sim \mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}-$
Imp-Lysine $>\mathrm{Zn}_{2} \mathrm{Al}$-LDH. Thus, AuNPs were essential for the photocatalysis and reconstructed AuNP-LDHs were basically superior to impregnated AuNP-LDHs. Among them, $\mathrm{Au} / \mathrm{Zn}_{2} \mathrm{Al}$-Rec-3-Light prepared via LDH reconstruction irradiated by UV-visible light was the best and totally photo-decomposed $50 \mathrm{mg} \mathrm{L}^{-1}$ of phenol in 160 min . In the catalyst, approximately 5 nm of $\mathrm{Au}^{0} \mathrm{NPs}$ were embedded on LDH surface through $\mathrm{Au}_{2} \mathrm{O}_{3}$ layers as revealed by $A u L_{3}$-edge XANES and EXAFS. Charges (electrons and holes) in the Au-LDH assembly separated by light were effectively diffused to $\mathrm{Au}^{0} \mathrm{NPs}$ and LDH surface and reduced $\mathrm{O}_{2}$ and proceeded indirect ring-opening mechanism to hydroquinone and then to p-benzoquinone, respectively. As the unsupported LDH negligibly photo-decomposed phenol, AuNPs were essential and directly incorporated in the catalysis. AuNPs impregnated on LDH under the UV-visible irradiation (not reconstruction route) or reduced using $\mathrm{NaBH}_{4}$ and/or lysine were less active and decomposed phenol via both indirect mechanism via p-benzoquinone and direct ring-opening mechanism to catechol, o-benzoquinone, and then to muconic acid.

## Acknowledgments

The authors are grateful for the financial supports from the Grant-in-Aid for Scientific Research C $(26410204,22550117)$ from Japan Science Promotion Agency, Japan and from the Romanian National Authority for Scientific Research, CNCS-UEFISCDI (PN-II-ID-PCE-75/2013), Romania. X-ray absorption experiments were conducted under the approval of the Photon Factory Proposal Review Committee (2014G631, 2012G683, 2011G033), Japan. The authors thank Shimadzu Corporation for the HPLC analyses.
